

Project Weak-Schur: Algorithm Proposal

Prasanna M.S.S

March 2022

The proposal is to develop a generic selection and fitness evaluation loop to create weakly sum-free partitions. The naive, single-threaded algorithm is proposed first, then simply extended to a multi-threaded algorithm. The Fitness function is then defined and simple bounds are given for it. These motivate an out-of-order selection, which is then detailed.

1 Process

The core Process of the algorithm can be summarised as a simple selection and fitness evaluation loop.

1.1 Single-Thread

```

Data:  $n \geq 0$ 
Result: BestSolution
Solutions  $\leftarrow \text{Dict}(\text{keys} : \{1 \dots n\});$ 
num  $\leftarrow 1;$ 
while BreakCondition(n, num, Choice) do
    num  $\leftarrow \text{num} + 1;$ 
    for  $\text{sol}_i \in \text{Solutions}$  do
         $\text{sol}_i.\text{append}(\text{num});$ 
         $\text{Fitness}[i] \leftarrow \text{EvaluateFitness}(\text{sol}_i);$ 
    end
    bestSolution  $\leftarrow$ 
        Choice(Solutions, Fitness);
end
```

Assume that the current search is for a Weak-Schur partition of n colours.

In the single-threaded implementation, Process will start by initialising the Dictionary of *Solutions*, and start a counter of the number to add in each iteration. Then, while *BreakCondition* is true, sol_i will add its number to the i^{th} colour, and evaluate the fitness. At the end of this evaluation, the best solution is chosen using a suitable *Choice* function.

Two remarks can be made here;

- The algorithm is general enough to permit us to change the *Choice* function easily to observe how the behaviour of the generated solutions

change. This allows us to experiment with a varied set of potentially multi-threaded or multi-process genetic algorithms. The *Choice* function also changes the *BreakCondition* in obvious ways.

- The inner *for*-loop of the algorithm can be embarrassingly parallel, and therefore can be split over multiple threads. This allows the algorithm to scale directly with the size of the partition being sought.

1.2 Multi-Thread

Following from the second remark, Process will start n threads to evaluate the *for* loop, in effect, one thread per sol_i or per color.

2 Fitness Function

2.1 Bounds

Definition 1. Let $S = \bigsqcup_i S_i$ be a weakly sum-free partition. The fitness of the partition is defined as

$$\text{fitness}(S) := \sum_{i \in [n]} |\{(a, b, c) \in S_i^3 : a + b = c, a \neq b \neq c\}| \quad (1)$$

Lemma 1. Let $S = \bigsqcup_i S_i$ be a weakly sum-free partition such that its size $|S| = \sum_i |S_i| = n$, and $\text{fitness}(S) = k$. Then, assume we add $N \in \mathbb{N} - S$ to S i.e. $\exists i \in [n] : S_i \leftarrow S_i \cup \{N\}$. Then, $\text{fitness}(S \cup \{N\}) \geq k$.

Proof. (Main) Assume we add $N \in \mathbb{N} - S$ to S i.e. $\exists i \in [n] : S_i \leftarrow S_i \cup \{N\}$.

Case 1 $\forall (a, b, c) \in S_i^3 : a + b = c, a \neq b \neq c \neq N$. This is the trivial case where no new pairs violating the sum-free property have been added, and so, $\text{fitness}(S \cup \{N\}) = \text{fitness}(S) = k$.

Case 2 $\exists(a, b, c) \in S_i^3, a + b = c, a = N \neq b \neq c$. Case 2 implies that at least one new pair has been added, and we have $\text{fitness}(S \cup \{N\}) > k$. Note that we can assume $a = N$ without loss of generality.

Case 3 $\exists(a, b, c) \in S_i^3, a + b = c, a \neq b \neq c = N$. this also implies that at least one new pair has been added, and we have $\text{fitness}(S \cup \{N\}) > k$.

□

Proof. (Alternate) Assume we add $N \in \mathbb{N} - S$ to S i.e. $\exists i \in [n] : S_i \leftarrow S_i \cup \{N\}$, and that $\text{fitness}(S \cup \{N\}) < k$. Then, there must exist at least one triplet $(a, b, c) \in S_i^3$ such that $a + b = c$, but $a + b \neq c$ when $(a, b, c) \in S_i^3 \cup \{N\}$. This is not possible when $a \neq b \neq c \neq N$, since no number was removed. However, supposing that $a = N$ or $c = N$ cannot be possible as $N \notin S_i$, but only in $S_i \cup \{N\}$. □

Lemma 2. Let $S = \bigsqcup_i S_i$ be a weakly sum-free partition such that its size $|S| = \sum_i |S_i| = n$, and $\text{fitness}(S) = k$. Then, suppose we add $N \in \mathbb{N} - S$ to S i.e. $\exists i \in [n] : S_i \leftarrow S_i \cup \{N\}$. Then, $\text{fitness}(S \cup \{N\}) \leq k + 2^{|S_i|+1} P_2$.

Proof. Adding N creates triplets of two types: 1) $(a, b, N) \in S_i^3$ such that $a \neq b \neq N$ and (2) $(N, b, c) \in S_i^3$ such that $N \neq b \neq c$ now violates the weakly sum-free property. There are at most $2 \cdot |S_i| + 1 P_2$ pairs of this form and we bound the number of pairs after the addition of $\{N\}$ as :

$$\begin{aligned} \text{fitness}(S \cup \{N\}) - \text{fitness}(S) &\leq 2 \cdot |S_i| + 1 P_2 \\ \implies \text{fitness}(S \cup \{N\}) &\leq \text{fitness}(S) + 2 \cdot (|S_i| + 1)(|S_i|) \end{aligned} \quad (2)$$

as desired. □

Since $\forall m, {}^m P_2 = O(m^2)$, this gives a good bound on the growth of fitness ; however, this may still be improved.

In summary, we have

$$\begin{aligned} 0 \leq \text{fitness}(S \cup \{N\}) - \text{fitness}(S) &\leq g(k_i) = O(k_i^2) \end{aligned} \quad (3)$$

where $k_i = \text{fitness}(S_i)$ so that g is a polynomial of order 2.

2.2 Out-of-order Selection

Out-of-order selection essentially presents the argument that in Alg. 1, $\text{num} \leftarrow \text{num} + 1$ can be replaced by a generic $\text{num} \leftarrow \text{getNumber}(\text{num})$ (This has the natural signature $\text{getNumber} : \mathbb{N} \rightarrow \mathbb{N}$).

This is immediately suggested by Lemma 1, where fitness , as shown to be a monotonically increasing function of the size of the partition n . Since no assumptions on the added number N were made, it holds true for any N that we add.

The proposal is to simulate and theoretically quantify the differences obtained when using such strategies. For example, $S = \{\{1, 2\}, \{3\}\}$ and $S = \{\{1, 3\}, \{2\}\}$ are both valid partitions using 2 colors, but may not lead to the same partitions over large iterations.

Therefore, if each coloring is a function $\text{Col} : \{1, \dots, N\} \rightarrow \{1, \dots, n\}$, where n is the number of colors, then understanding out-of-order selection can help us choose better maps Col .

2.3 Multi-Process Algorithm

After motivating an out-of-order selection, Alg. 2 details the multi-process algorithm with getNumber .

Data: $n \geq 0, m \geq 1$

Result: BestSolution

$\text{Solutions} \leftarrow \text{Dict}(\text{keys} : \{1 \dots m\}, \text{values} : \text{Dict}(\text{keys} : \{1 \dots n\}))$;

while $\text{BreakCondition}(n, \text{num}, \text{Choice})$ **do**

for Process_j in ProcessPool **do**

$\text{num} \leftarrow \text{getNumber}(\text{num}, j)$;

for $\text{sol}_i \in \text{Solutions}[j]$ **do**

$\text{sol}_i.\text{append}(\text{num})$;

$\text{Fitness}[j][i] \leftarrow$

$\text{EvaluateFitness}(\text{sol}_i)$;

end

$\text{BestSolutions}[j] \leftarrow$

$\text{Choice}(\text{Solutions}[j], \text{Fitness}[j])$;

end

$\text{BestSolution} \leftarrow$

$\text{Choice}(\text{BestSolutions}, \text{Fitness})$;

end
